International Seminar on Public Health and Education

2018
PREFACE

The 4th International Seminar on Public Health Education (ISPHE 2018) was held on The Wujil Resorts and Conventions, Semarang, Indonesia on May 8-9 2018 by the Faculty of Sports Science Universitas Negeri Semarang. The 328 scientific participants, 163 of whom were students, had many fruitful discussions and exchanges that contributed to the success of the conference. The 251 abstracts including poster session that were presented on the first two days formed the heart of the conference and provided ample opportunity for discussion. The abstracts were split almost equally between the four main conference areas, i.e.; Interdisciplinary Health and Medicine, Physiology, Kinesiology and Psychology of Wellness, Public Health Policies and Practices, and Health Promotion and Physical Education.

Of the total number of presented abstracts, 16 of these are included in this proceedings volume. Other publication options are 3 respectable scientific journals and one national proceedings. The review procedure was thoroughly done by two blind reviewers have reviewed each paper from the participant. There were 4 plenary lectures covering the different areas of the conference: Prof. Chia-Hua Kuo. Ph.D. (Dean of Research and Development University of Taipei, Taiwan) talked about the latest research on nutrition and food metabolism, Dr. Toru Okuwaki (Japan Institute of Sports Sciences) for sports development in Japan, Dr. Mahenderan Appukutty (Head of Postgraduate Studies UiTM, Malaysia) for nutritional science of early childhood and last are Dr. Sugeng Eko Irianto (WHO Representative of the Republic of Indonesia) and Prof. Dr. dr. Oktia Woro Kasmin Handayani, M.Kes (Universitas Negeri Semarang, Indonesia) on health and nutrition status in Indonesia.

Generous support for the conference was provided by the Indonesian Public Health Association (IAKMI) and some prominent Indonesia universities in health education and sport (Malang State University, Gorontalo State University, and Manado State University). The next ISPHE will take place in Semarang in 2020, and the ones after that will be in Malang in 2022 and Gorontalo in 2024. Given the rapidity with which science is advancing in all of the areas covered by ISPHE, we expect that these future ISPHE conferences will be as stimulating as this most recent one was, as indicated by the contributions presented in this proceedings volume.

Changes In Blood Sugar Level After Cycling For 30 Minutes

1st Ramdulan Pelana  
Faculty of Sport Science  
Universitas Negeri Jakarta  
Jakarta, Indonesia  
ramdulpelana@unj.ac.id

Abstract—The purpose of this study is the change in blood sugar levels after cycling for 30 minutes. This was an experimental study. The criteria of this study are 17 years old, weight 50-55kg, glucose level 110-140mg/dl. The results of the calculation of blood glucose values before and after cycling obtained the difference of average 25.2. The calculation states that there is a decrease in blood sugar level after doing the cycling activity for 30 minutes.

Keywords—blood sugar level, diabetes, insulin, cycling 30 minutes introduction

I. INTRODUCTION

A series of our daily activities make it difficult for many people to do sports in the midst of our busy routine, whereas good exercise needed to maintain our fitness. Health should be maintained because healthy is expensive, many people have high wealth and position but can not enjoy it because his body is no longer healthy because of the wrong lifestyle. Many people consume high-calorie foods but not balanced with physical activity often cause various health problems such as diabetes.

Diabetes is a disease that needs to be aware of. Most people realize they have diabetes after they are aged. Diabetes is one of the diseases that arise due to poor lifestyle. The World Health Organization (WHO) estimates that 177 million people worldwide suffer from diabetes [15].

Sekolah Menengah Atas Negeri 3 Serang is one of the public high schools in Serang city that has implemented Full Day School and has a fairly solid academic routine for their students. The students of SMAN 3 Serang start the lesson at 07.00 a.m. until 15.30 p.m.

SMAN 3 Serang is one of the public schools in Serang City that uses domicile system in the selection of their new students. A total of 30% seats are reserved for those who live in areas close to SMAN 3 Serang.

Blood is a body fluid that flows in the blood vessel system found in humans and animals. Blood sugar contained in the body is produced by foods that contain carbohydrates, proteins, and fats. Blood is a vehicle or medium to transport various nutrients throughout the body. Blood functions in transporting oxygen, nutrients and metabolic waste from the heart to the whole body and back to the heart [16].

All types of carbohydrates that are consumed by human beings are either complex carbohydrate types (rice, potatoes, bread, cassava etc) or simple carbohydrates (glucose, sucrose, fructose) will be converted into glucose in the body. This formed glucose can then be stored as energy reserves as glycogen in the liver and muscles and can be stored in the blood or can also be brought into the cells of the body in need [17].

Glucose contained in the bloodstream is what is referred to as blood sugar levels. Glucose levels in arteries is 15-30 mg / dl higher than in veins. Blood glucose concentration or glucose level is tightly regulated in the body. Glucose that stream throughout the body is the main source of energy for the body's cells.

Heart Glucostat. The liver has the ability to maintain blood sugar concentrations in order to remain normal in some circumstances. During exercise, muscle calorie needs are initially filled with glycogenolysis in the muscle and increased glucose uptake. Plasma glucose is initially elevated due to increased glycogenolysis of the liver but may decrease due to heavy and prolonged exercise [5].

The plasma glucose level at one time is determined by the balance between the amount of glucose that enters the bloodstream and the amount that leaves it. Five percent of glucose consumed directly in conversion to fat. The rest is metabolized in muscles and other tissues. At the time of fasting, the liver glycogen is disport and the liver adds glucose to the bloodstream. If the fast is longer, glycogen runs out and there is an increase in gluconeogenesis of amino acids and glycerol in the liver. There is a moderate decrease in plasma glucose to about 60 mg / dl during prolonged hunger in normal people, but no symptoms of hypoglycemia occur because gluconeogenesis prevents further reduction.
Table 1. Blood Glucose Levels in Several Circumstances and Times

Thus, William F. Ganong points out that the liver functions as a kind of "glucoseat", which will maintain blood sugar levels. The liver can also help dispart fructose and galactose into glucose and glucose into fat. This can happen because of hormonal activity secreted by the islets of Langerhans in the pancreas. Two of these hormones, insulin and glucagon, have important functions in regulating metabolism between carbohydrates, proteins and fats. The third hormone, somatostatin plays a role in regulating the secretion of the islets of Langerhans cells, and the fourth physiological function of the hormone, the pancreatic polypeptide is unknown [6].

The hormones that play an important role in the regulation of blood sugar levels to remain in normal circumstances: Insulin. Insulin is a hormone that is naturally secreted by the pancreas into the bloodstream and then circulates throughout the body. The function of insulin is to help blood sugar entering the cells. If insulin is very little even none or can not function normally, then the sugar can not get into the cell. As a result sugar can not be used to make energy. This situation causes cells to starve.

The main regulator of insulin secretion is induced by the direct feedback effect of blood sugar levels on the pancreas. Glucose permeates the islets of the Langerhans easily and the rate of income is not influenced by insulin. If blood sugar levels that promote pancreas increase (in mice above 110 mg / dl), insulin secretion in the blood of the pancreatic venous increases, if the levels are normal or low, the speed of insulin secretion is slow.

Insulin is an anabolic system, increasing the deposits of glucose, fatty acids and amino acids. Inclusion of glucose into the skeletal muscle increases without insulin. Insulin facilitates the entry of glucose into cells by increasing the number of glucose transporters in the cell membrane.

Without insulin, the entry of glucose into the skeletal muscle may increase during exercise. Doing regular exercise can result in a prolonged increase insulin sensitivity. Exercise can also cause hypoglycemia due to increased glucose uptake in the blood. Sugar that can not enter the cells will be in high concentrations in the blood, if it lasts long it can cause diabetes.

Glucagon is glycogenolytic, gluconeogenic, and lipolytic. It increases blood sugar because it stimulates adenylyl cyclase in liver cells. Adenylyl cyclase tends to activate phosphorylase therefore it increase the breaking of glycogen. Like insulin, glucagon is a protein hormone produced in the pancreas, glucagon is an insulin balancer.

Glucagon is also catabolic, mobilizing glucose, fatty acids and amino acids from its reserves into the blood. Approximately 4-6 hours after eating, the level of glucose in the blood is reduced. This triggers the production of glucagon in the pancreas, when the pancreas secretes insulin glucagon will be pressed. Glucagon signs the liver and muscles to dispart glycogen into glucose and pull it back into the bloodstream, keeping your blood sugar levels low.

Eating proteins and infusing various amino acids increases glucagon secretion. It seems that in this case, what suitable and potent are gluconeogenic amino acids, because they are amino acids that are converted into glucose in the liver under the influence of glucagon. Increased glucagon secretion after eating protein is also beneficial, as amino acids stimulate insulin secretion, and the secreted glucagon prevents the development of hypoglycemia while insulin facilitates the storage of absorbed carbohydrates, fats and lipids. Glucagon secretion increases hungre time. It reaches its peak on the third day of fasting, at the time of maximum gluconeogenesis. After that, plasma glucagon levels decrease the time fatty acids and ketones become the main source of energy.

Glucagon does not cause glycogenolysis in the muscles. It increases the gluconeogenesis of the amino acids available in the liver and increases the speed of its metabolism. These two hormones between insulin and glucagon are opposite in their ways of working, and in many cases are secreted in opposite ways.

Cycling is one of the best activities to improve heart fitness. Heart fitness is measured by aerobic capacity, ie the ability to exercise large muscles and whole bodies at moderate to high intensity levels for long periods of time [4].

Cycling becomes the best way to practice for 20 to 30 minutes every day, 3 to 5 days each week to get good health and wellness. In Bikemania, it is explained that the human body is designed to move. Research has shown that exercising regularly for 30 minutes in one day provides many benefits, even though the 30 minute time is divided into two or three different sessions. If you are over 40 years of age, being overweight or never exercising regularly for long periods of time, it is important that you consult your doctor first before starting a cycling program [8].

Cycling is identic with physical activity or physical exercise that can be done by everyone. Physical activity includes activities that involve body movement. Therefore, cycling can spur heart rate in accordance with the target we want. Physical activity such as sport is one form of work. To be able to do work like exercise our body needs energy.

When we exercise (cycling), muscle energy requirements are initially fulfilled by muscle glycogenolysis, after the glycogen in the muscle is reduced there will be an increase in glucose uptake in the blood. Plasma glucose initially falls due
to muscle retrieval but may return to normal due to
glycogenolysis of the liver (liver glucostat).

Fulfillment of energy during physical activity is obtained
through metabolic processes. Metabolism is a chemical process
that allows cells to survive. In general, sports activities consist
of two types of activities: aerobic activity and anaerobic
activity. Aerobic activity is a low to moderate intensity exercise
activity that can be done continuously and over long periods of
time.

Aerobic exercise involves large muscle groups and is
performed in moderately low intensity, as well as in
considerable time. Aerobic exercise is maintained from 15 - 20
minutes to several hours in a single exercise [11].
The formation of energy in the muscle is as follows:

- Aerobics
- Glycogen and free fatty acids + P + ADP + O2 $\leftrightarrow$ CO2 + 
  H2O + ATP.
- Anaerobic
  1. ATP$\rightarrow$ ADP + P + Free energy
  2. Creatine phosphat + ADP $\leftrightarrow$ Kreatin + ATP
  3. Glycogen / Glucose + P + ADP $\leftrightarrow$ Lactate Acid + ATP

Aerobic exercise can be done with low to moderate intensity
cycling. Here are some models of cycling exercises in low
intensity zones and short periods of time.

The use of energy at various cycling speeds is more or less
as follows [13]:

<table>
<thead>
<tr>
<th>Speed</th>
<th>Distance</th>
<th>Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>9.6 km/hr</td>
<td>270 Kal/hr</td>
<td>20 minutes</td>
</tr>
<tr>
<td>12.8 km/hr</td>
<td>330 Kal/hr</td>
<td>20 minutes</td>
</tr>
<tr>
<td>16 km/hr</td>
<td>400 Kal/hr</td>
<td>20 minutes</td>
</tr>
<tr>
<td>17.6 km/hr</td>
<td>450 Kal/hr</td>
<td>20 minutes</td>
</tr>
<tr>
<td>19.2 km/hr</td>
<td>550 Kal/hr</td>
<td>20 minutes</td>
</tr>
<tr>
<td>20.8 km/hr</td>
<td>650 Kal/hr</td>
<td>20 minutes</td>
</tr>
</tbody>
</table>

Cycling for 30 minutes at a speed of 26 km / h then there
will be a working effect that will affect the concentration of
blood sugar levels. Blood sugar in the blood will decrease due
to increased glucose uptake in the muscle but blood sugar levels
will return to normal conditions due to the presence of the liver
as glucostat that keep blood concentration levels.

The following is the number of normal pulses per minute:
1. Infants up to 1 year of age: 100 - 150 times per minute
2. Children aged 1-10 years: 70 - 130 times per minute
3. Children aged 10-18 years: 60 - 100 times per minute
4. Adults: 50 - 80 times per minute (Evelyn C Pearce, 1999).

Measuring maximum pulse rate

Formula: 220 - Age

Example: 220 - 17 = 203 / min.

Measuring Activity Percent

After doing the activity cycling with a speed of 26 km / h
and a distance of 13 km, then measured again his pulse and
pulse rose to 130 - 135 / minutes.

Formula:

Activity Pulse / Pulse Maximum x 100%
= 130/203 x 100
= 65%

Thus, with a speed of 26 km / h and a distance of 13 km.
The effort performed shows the pulse of activity 65% of
maximum activity / maximum pulse rate.

8. Ballpoint
9. 10 units of mountain bikes using 3 gear
10. 4 tester.

Data Collection Technique. In this study the data was taken by measuring blood sugar levels by 20 people testee, then testee do a blood sugar measurement test after fasting for 2 hours and after biking for 30 minutes with the following implementation procedures:
1. The sample is divided into 2 groups, the first group breakfast at 07.00 am and the second group at 07.30 pm.
2. Samples taken blood glucose level 2 hours after meal, first group at 09.00 pm and second group at 09.30 pm.
3. Samples sit relaxed to the blood taken as much as one drop.
4. At first, prepare the glucometer tool along with chips and needle.
5. Then select one of the sample fingers and wipe with a cotton containing alcohol to sterilize.
6. Adjust the length of the needle according to the sample skin thickness. Then puncture until the blood comes out. And input the blood into the chip on the glucometer.
7. Wait for the result from the glucometer tool then record the result.
8. After the initial data obtained then the sample cycled with a speed of 26 km / hr crossing the road to SMAN 3 Serang with a travel time of 30 minutes and mileage of approximately 13 km.
9. After 30 minutes of cycling, the sample stops and will be retrieved immediately (post test).
10. Then select one of the sample fingers and wipe with a cotton containing alcohol to sterilize.
11. Adjust the length of the needle according to the sample skin thickness. Then puncture until the blood comes out. And input the blood into the chip on the glucometer.
12. Wait for the result of the glucometer tool and record the result.
13. Samples are not allowed to consume anything since the initial test (pre test) until completion of the final test (post test).

III. RESULT AND DISCUSSION

A. Description
Data collected at the time of the study was used as research data obtained from the initial test and the final test of blood sugar levels. The data can be described as:
<table>
<thead>
<tr>
<th>Variable</th>
<th>Initial Blood Sugar Level (mg/dl)</th>
<th>Final Blood Sugar Level (mg/dl)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum Value</td>
<td>132</td>
<td>111</td>

IV. CONCLUSION

Based on the problems presented and supported by the theoretical descriptions, existing research data, and analysis of data that has been done, it can be concluded that: There is a 30-minute cycling effect on the change of blood sugar levels in students of grade XI SMAN 3 Serang.

REFERENCES

B. Hypothesis testing

The average score of the results obtained at the initial test was 121.7 mg / dl and in the final test of 96.5 mg / dl. From the average data on the initial test and the final test on blood sugar tests showed a decrease in the results obtained. From result of data analysis obtained difference of mean 25.2 with standard deviation difference (SDd) that is equal to 5.02 and standard error difference average equal to 1.15 in subsequent calculation obtained t-count equal to 21.91 and t-table value with degree of freedom (n-1) and significant level of α = 0.05 is 2.09. Since the t-count is greater than the t-table value, it indicates that (H0) is rejected and (H1) is accepted.

This means that the results of the calculation stated that the activity of cycling for 30 minutes can lower blood sugar levels in students of class XI SMA Negeri 3 Serang.
